The effect of parent characteristics on the development of child-obesity. Child-obesity is one of the most serious health problems of the 21st century. Obesity is influenced by several environmental and individual factors. However, the role of parent's body mass index (BMI) on children's body weight is not clear yet. Thus, we aimed to investigate the influence of parental BMI on childhood obesity. This case-control study was conducted on 685 obese and 685 non-obese healthy children. Parental BMI was higher in the obese children's family and there was no significant difference between fathers and mothers of obese and non-obese children. The most frequent paternal BMI and parental BMI were over 25 and 24, respectively. Multiple regression analysis showed that paternal BMI ($B = 0.07$; $P = 0.049$), mother's job ($B = 0.08$; $P = 0.04$) and child's birth weight ($B = 0.34$; $P = 0.000$) were independently associated with obesity, but there was no significant relationship between paternal and maternal BMI and obesity. Parental BMI should be considered as a risk factor of childhood obesity, particularly when the parents have high BMI.
